

Claude Code Handoff: VVV On-Chain Intelligence + OpenClaw Migration Dashboard

Context

I'm building a Dune Analytics dashboard for VVV (Venice AI token) on Base chain. It has two purposes:

1. **Market intelligence** — An ERC-20 adaptation of Glassnode's STH-NUPL / STH-SOPR framework, originally built for FAI (Freysa) and now ported to VVV. Panels 1-8 cover new entrant cost basis, CEX netflows, holder cohorts, whale tracking, DEX buy/sell ratio, staking flows, and DIEM activity.
2. **OpenClaw migration tracking** — On April 4, 2026 at 12pm PT, Anthropic banned Claude subscriptions from being used with third-party agent frameworks like OpenClaw. Venice AI is OpenClaw's recommended model provider. Panels 9-10 are specifically designed to detect and quantify on-chain evidence of displaced OpenClaw agent operators migrating to Venice by staking VVV and minting DIEM for compute access.

The attached `vvv_dune_dashboard.md` contains 10 panels with 17 SQL queries. Read it fully before doing anything.

What Already Exists

- A Python `NewEntrantPnLSignal` module in `fai_derivatives_signals.py` within `F:/Projects/signal-command-center/` that does STH-NUPL analysis locally via BaseScan API. The Dune dashboard is the public-facing version.
- My signal-command-center Flask API runs on port 8878 — the Dune dashboard is standalone, not integrated into the local stack.
- DIEM contract address on Base: `0xf4d97f2da56e8c3098f3a8d538db630a2606a024` (confirmed from Venice blog post about Aerodrome trading pair).

Phase 1: Resolve Contract Addresses (CRITICAL — do this first)

1. **sVVV (staked VVV) contract address on Base.** Check:
 - BaseScan token page for VVV (`0xacFE6019Ed1A7Dc6f7B508C02d1b04ec88cC21bf`) —

look at top token holders or approval/transfer patterns to identify the staking contract

- Venice docs at venice.ai/blog/introducing-the-venice-token-vvv or venice.ai/blog/understanding-venice-compute-units-vcu
- The Venice token dashboard at venice.ai/token
- BaseScan verified contracts search for "Venice" or "sVVV"

2. **Verify DIEM contract:** `0xf4d97f2da56e8c3098f3a8d538db630a2606a024` — confirm this is active on Base and check that mint events (transfers from 0x0) exist.

3. **Replace ALL placeholder addresses** in the dashboard MD:

- `0x__STAKING_CONTRACT_ADDRESS__` → actual sVVV address (appears in Panels 4, 9A, 9B, 10C)
- `0x__DIEM_CONTRACT_ADDRESS__` → confirmed DIEM address (appears in Panels 6, 10A, 10B, 10C)

Phase 2: Validate Query Syntax for DuneSQL (Trino)

Review each query against Dune's current schema. Key tables and expected columns:

Table	Key Columns	Notes
<code>tokens.transfers</code>	<code>blockchain,</code> <code>contract_address,</code> "from", "to", <code>amount,</code> <code>block_time</code>	Partition by <code>blockchain</code> + <code>block_time</code> range for performance
<code>prices.usd</code>	<code>blockchain,</code> <code>contract_address,</code> <code>minute,</code> <code>price</code>	May have gaps for VVV — fallback to <code>prices.day</code> or <code>dex.prices</code>
<code>balances.erc20_latest</code>	<code>blockchain,</code> <code>token_address,</code> <code>address,</code> <code>balance</code>	Derived from cumulative transfers, may lag
<code>labels.addresses</code>	<code>blockchain,</code> <code>address,</code> <code>category,</code> <code>name</code>	Check if <code>category =</code> 'cex' works on Base — may need different filter

<code>dex.trades</code>	<code>blockchain , token_bought_address , token_sold_address , amount_usd , taker , block_time</code>	Covers Aerodrome + Uniswap V3 on Base
-------------------------	---	--

Common DuneSQL (Trino) issues to check:

- Address literals: should be `0x...` as varbinary, not quoted strings
- `APPROX_PERCENTILE` is correct for Trino
- `SEQUENCE()` + `UNNEST()` for date series generation
- `FILTER (WHERE ...)` syntax is valid in Trino
- `DATE_DIFF` function syntax may differ — check Trino docs
- Add `block_date` partition filters where missing for query performance

Phase 3: Supplement CEX Address List

Dune's `labels.addresses` on Base is likely thin. For Panel 2 (CEX Netflows), create a hardcoded CTE of known exchange hot wallets on Base. At minimum find:

- **Coinbase** hot wallets on Base (primary VVV exchange — they have multiple)
- **Kraken** if active on Base
- Check BaseScan's "Exchange" label on the VVV token holders page
- Cross-reference with the top VVV holders list — exchanges will be obvious by balance size and transfer frequency

Add these as a supplementary CTE that UNIONS with the `labels.addresses` results.

Phase 4: Migration Panel Validation (Panels 9-10)

These panels are the most novel and important. Specific things to verify:

1. **Panel 9A/9B** — The ban timestamp is April 4, 2026 at 12pm PT = **19:00 UTC**. Ensure the `POST_BAN` classification uses this exact timestamp, not just the date.
2. **Panel 10A** — The `mint_acceleration_ratio` is the headline migration metric. Verify the window function logic: each day's DIEM minted divided by the trailing 7-day average (excluding current day). A ratio > 2x is notable, > 5x is a wave.

3. **Panel 10C** — The conversion funnel (buyers → stakers → minters) requires joining across three different queries. Verify that the post-ban date filter is consistent across all three CTEs.
4. All migration panels should start from `DATE '2026-03-01'` to capture 30+ days of pre-ban baseline data for comparison.

Phase 5: Deployment (Optional)

If feasible, create a Python script using `dune-client` that:

1. Creates each query via the Dune API
2. Outputs query IDs for manual dashboard assembly
3. Sets refresh intervals: 30 min for STH-NUPL panels, 5 min for CEX flows, 1 hour for migration panels

If the Dune API doesn't support programmatic dashboard creation, just output a mapping of query names → query IDs.

Key Technical Details

Item	Value
VVV Contract (Base)	<code>0xacFE6019Ed1A7Dc6f7B508C02d1b04ec88cC21bf</code>
DIEM Contract (Base)	<code>0xf4d97f2da56e8c3098f3a8d538db630a2606a024</code>
sVVV Contract (Base)	NEEDS LOOKUP
Token Decimals	18 (VVV and DIEM)
Primary DEX	Aerodrome (Base), Uniswap V3
Primary CEX	Coinbase
Dune Engine	DuneSQL (Trino-based)
Ban Timestamp	April 4, 2026, 19:00 UTC

Thresholds (Do Not Modify)

STH-NUPL (validated in FAI analysis):

- EUPHORIA: 80%+ of 72hr wallets at >40% unrealized gain
- GREED: 60%+ at >25% gain
- FEAR: 50%+ underwater
- CAPITULATION: 70%+ at >20% loss

Migration signals (new):

- Migration wave: DIEM mint acceleration > 5x
- Migration notable: DIEM mint acceleration > 2x
- New staker spike: Daily first-time stakers > 3x pre-ban average
- Funnel conversion: >30% of post-ban VVV buyers also stake within 7 days
- Compute consumer quality: Avg DIEM per new minter > 1.0 (\$1+/day)

Success Criteria

- All 17 queries execute without errors on Dune
- sVVV contract address resolved and populated in all panels
- DIEM contract address verified and populated
- CEX address list supplemented beyond `labels.addresses`
- STH-NUPL gauge (Panel 1B) returns a single regime classification
- CEX netflow (Panel 2A) shows directional flow with USD values
- Migration panels (9-10) correctly split data at April 4 19:00 UTC
- DIEM mint acceleration ratio (Panel 10A) computes correctly against trailing 7-day avg
- Conversion funnel (Panel 10C) returns three stages with post-ban counts

Workflow Preference

Explore → Plan → Build. Read the full `vvv_dune_dashboard.md` first, investigate contract addresses and Dune schemas, make a plan, then execute edits. Do not modify STH-NUPL thresholds.

Research Context (for understanding the “why”)

On April 4, 2026, Anthropic blocked Claude Pro/Max subscriptions from powering OpenClaw and other third-party agent frameworks. OpenClaw had ~135K active instances, many running on subsidized \$20/month Claude subscriptions that consumed \$1,000–5,000/day in equivalent API costs. Venice AI is OpenClaw's officially recommended model provider (since March 2026). Venice's DIEM token provides \$1/day of perpetual API compute credit per token — making it the only option where displaced agent operators can lock in fixed compute costs permanently rather than renting from another provider subject to future pricing changes. This dashboard exists to provide on-chain proof of whether that migration is actually happening.
